2 Theoretical background

While the main focus of this bachelor project is the numerical modeling of waves in the solar corona, some theoretical background is important to frame the results of our simulations. Furthermore, this knowledge gives some insight in the assumptions that are made in deriving the magnetohydrodynamic (MHD) equations and when they are valid.

Hydrodynamics

2.1 Hydrodynamic fluid equations

The theory in this section is adapted from [notes-fluid-dynamics]. For the first task a non-viscous Newtonian fluid is considered. Heat conduction and dissipation is neglected as well. This type of fluid obeys the Euler equations for conservation of mass, momentum and internal energy:

$$\begin{aligned}\frac{d\rho}{dt} + \rho \nabla \cdot \vec{v} &= 0 \\ \rho \frac{d\vec{v}}{dt} &= -\nabla p + \vec{F} \\ \frac{dp}{dt} - \frac{\gamma p}{\rho} \frac{d\rho}{dt} &= 0\end{aligned}\tag{1}$$

These are the Euler equations in Lagrangian form, with time derivatives following the fluid, hence the total derivatives with respect to time. PLUTO does the fluid simulation using a static grid, so we need the equations in Eulerian form with partial derivatives with respect to time. This change of derivatives can be carried out using the following relation, found in [notes-fluid-dynamics] in section 2.4:

$$\frac{df}{dt} = \frac{\partial f}{\partial t} + (\vec{v} \cdot \nabla) f\tag{2}$$

where $f(x, y, z, t)$ is a function that describes a property of the fluid. The equations can also be rederived using an Eulerian view. In any case the result is the same:

$$\begin{aligned}\frac{\partial \rho}{\partial t} + \nabla \cdot (\rho \vec{v}) &= 0 \\ \frac{\partial}{\partial t} (\rho \vec{v}) &= \nabla \cdot (-p - \rho \vec{v} \vec{v}) + \vec{F} \\ \frac{\partial}{\partial t} \left(\rho \left(\frac{\vec{v}^2}{2} + \mathcal{U} \right) \right) &= \vec{F} \cdot \vec{v} - \nabla \cdot \left(\rho \left(\frac{\vec{v}^2}{2} + \mathcal{U} \right) \vec{v} + p \vec{v} \right)\end{aligned}$$

Next introduce the variable $\vec{m} = \rho \vec{v}$, the momentum density. The energy density \mathcal{U} can be split in the thermal energy ρe and gravitational potential energy $\rho \Phi$. Let $E_t = e\rho + \frac{\vec{v}^2}{2}$. The only external force is $\vec{F} = \rho \vec{g}$ carrying out these substitutions leads to the equations in section 6 in the PLUTO manual [pluto-manual]:

is the expression for \vec{F} correct? Looks to be different in equation 2 and 3

$$\begin{aligned}
\frac{\partial \rho}{\partial t} + \nabla \cdot \vec{m} &= 0 \\
\frac{\partial \vec{m}}{\partial t} + \nabla \cdot (\vec{m} \vec{v} + p) &= -\rho \nabla \Phi + \rho \vec{g} \\
\frac{\partial}{\partial t} (E_t + \rho \Phi) + \nabla \cdot ((E_t + p + \rho \Phi) \vec{v}) &= \vec{m} \cdot \vec{g}
\end{aligned} \tag{3}$$

Together with an equation of state $\rho e = \rho e(p, \rho)$, which gives the thermal energy as a function of p and ρ . In the remainder of this paper a calorically ideal gas is assumed. This is a gas for which the adiabatic constant γ obeys:

$$\gamma = \frac{f + 2}{f} \tag{4}$$

where f is the number of degrees of freedom. the previous relation can be rewritten as

$$f = \frac{2}{\gamma - 1}$$

And by substituting this equation in the equation that expresses the energy as a function of degrees of freedom the closure relation $\rho e = \rho e(\rho, p)$ is found: _____

Add a reference for this energy equation

$$E_t = \rho e = \frac{f}{2} n k_B T = \frac{p}{\gamma - 1}$$

short discussion of assumptions made (no viscosity and heat conduction, calorically ideal gas)

afleiding golven, groepsnelheid

2.2 Hydrodynamic linear waves

We start again from the ideal fluid equations as given in [Equation 1](#) and linearize them. For this we rewrite the quantities ρ and p as a background density ρ_0 and pressure p_0 with slight deviations ρ' , p' . Furthermore it is assumed that there are no external forces acting on the fluid. The Linearized equations are:

$$\begin{aligned}
\frac{\partial \rho'}{\partial t} + \rho_0 \nabla \cdot \vec{v} &= 0 \\
\rho_0 \frac{\partial \vec{v}}{\partial t} &= -\nabla p' \\
\frac{\partial p'}{\partial t} &= \frac{\gamma p_0}{\rho_0} \frac{\partial \rho'}{\partial t}
\end{aligned} \tag{5}$$

By acting with ∇ on the second equation and using the first to substitute $\rho_0 \nabla \cdot \vec{v}$ we find the following relation:

$$\frac{\partial^2 \rho'}{\partial t^2} = -\nabla^2 p'$$

Acting with $\frac{\partial}{\partial t}$ on the last equation and substituting the previous expression yields

$$\frac{\partial^2 p'}{\partial t^2} + \frac{\gamma p_0}{\rho_0} \nabla^2 p' = 0$$

which is the wave equation with $v_s = \sqrt{\frac{\gamma p_0}{\rho_0}}$ the phase speed of the wave. Similar expressions are found for the other variables. this wave speed can be found by substituting a plan wave of the form _____

Referentie?

$p' = A \exp(i(\omega t - \vec{k} \cdot \vec{x}))$. Substituting this expression in the wave equation for p' leads to the dispersion relation:

$$\omega^2 = k^2 v_s^2. \quad (6)$$

The phase velocity is given by

$$v_{ph} = \frac{\partial \omega}{\partial k} = v_s \quad (7)$$

from which we conclude that these waves are non-dispersive.

2.3 Hydrodynamic shocks

Now we shall reconsider one of the least convincing assumptions made for the derivations of the fluid equations: that of perfectly continuous background variables. In reality, we might encounter very sudden changes in the scalar variable density ρ and vectorial variable velocity \vec{v} . To have the theory of ideal fluids take this into account, we can introduce these jumps in the variables as mathematical discontinuities. This discontinuity is appropriately called a 'shock'. We are interested in how this shock moves through the fluid. The derivation of its motion is quite straight forward.

Start from the continuity equation in its Eulerian form in 1D

$$\frac{\partial \rho}{\partial t} + \frac{\partial(\rho v)}{\partial x} = 0 \quad (8)$$

Of course, this equation assumes that ρ and ρv are continuous variables with continuous partial derivatives. Rewrite the equation so that over a distance Δx and a duration Δt the variables ρ and ρv experience a change $\Delta \rho$ and $\Delta \rho v$. This gives the much less elegant version

$$\frac{\Delta \rho}{\Delta t} + \frac{\Delta(\rho v)}{\Delta x} = 0 .$$

If this were the perfectly continuous case we would now let $\Delta x, \Delta t \rightarrow 0$, resulting in [Equation 8](#). However, we might also say that the transition is not smooth and that for $\Delta x, \Delta t \rightarrow 0$ the jump remains: $\Delta \rho, \Delta \rho v \rightarrow \Delta \rho, \Delta \rho v$. Rewrite the equations to see what this means:

$$\frac{\Delta x}{\Delta t} \Delta \rho + \Delta(\rho v).$$

Then for $\Delta x, \Delta t \rightarrow 0$ we get

$$\frac{\partial x}{\partial t} \Delta \rho + \Delta(\rho v) = -V_S \Delta \rho + \Delta(\rho v) = 0 \quad (9)$$

where V_S is the shock speed. This relation is the hydrodynamic shock condition. To generalize it beyond 1D, it suffices to take $\vec{v} \cdot \vec{n}$ instead of v where \vec{n} is the unit normal vector on the shock wave front pointing towards the region with lower pressure. It looks as follows

$$-V_S \Delta(\rho v) + \Delta(\rho \vec{v} \cdot \vec{n}) = 0 . \quad (10)$$

The minus sign in front of V_S is merely a matter of orientation. In [Equation 9](#) the orientation is along the positive x-axis. In [Equation 10](#) it is along the unit vector \vec{n} . This is the first of the three *Rankine-Hugoniot* relations. The other two can analogously be derived from the Eulerian form of momentum and energy equations in [Equation 1](#). The three Rankine-Hugoniot conditions are

$$\begin{aligned}
V_S \Delta \rho &= \vec{n} \cdot \Delta(\rho \vec{v}) \\
V_S \Delta(\rho \vec{v}) &= \vec{n} \cdot \Delta(\rho \vec{v} \vec{v} + p \mathbf{I}) \\
V_S \Delta E_t &= \vec{n} \cdot \Delta\left(\rho \left(e + \frac{v^2}{2} + \frac{p}{\rho}\right) \vec{v}\right)
\end{aligned} \tag{11}$$

Derivation of MHD equation, discussion of the integration scheme used

2.4 Magnetohydrodynamic fluid equations

There are two approaches commonly taken in the literature to derive the MHD equations. They are either derived from kinetic gass theory, or postulated with added justification of why they can accurately describe plasmas.

A plasma is an ionised gas consisting of positive and negative ions. In the case of the corona of the sun this is mainly ionised hydrogen. Therefore the negative ions are free electrons and the positive ions protons, which are a lot heavier than electrons. When the characteristic timescales τ_e and τ_i between two collisions of electrons, respectively ions, is much shorter than characteristic timescales τ_f at which macroscopic variables change we can use a fluid description. At these timescales the individual interactions of individual particles are not relevant anymore.

The plasma can then be described as two different fluids, commonly referred to as the *two-fluid theory*. The electron gas is one fluid and the proton gas the other. The next assumption that is made, is that the relaxation time τ_T until the electron fluid and ion fluid are in thermal equilibrium after a slight disturbance is also a lot smaller than τ_f . Finally, we assume that the fluid has no net charge. Not globally, but also not locally. This means that in every large enough volume, for every ion with charge Z , there are also about Z electrons in this volume. When all this applies, the variables describing the different fluids can be averaged or added together, to describe the plasma as one fluid.

add reference to cursus Poedts and course notes arxiv

The MHD equations can then be found by adding the maxwell equations to the HD equations. Because the HD equations are invariant under Galilean transformations. However the Maxwell equations are invariant under Lorentz transformations, so we cannot simply add them to the HD equations and expect a consistent picture. Understanding the averaging process is important for understanding what the plasma variables actually represent. Denote with n_α the number density of a certain type of particle, m_α the mass, \vec{u}_α the velocity of a fluid element and with p_α the pressure of the gas of these particles. Let the subscript e denote variables concerning the electron gas and i variables describing the ion gas. The variables describing the plasma are the following linear combinations of variables describing the electron and ion gas:

$$\begin{aligned}
\rho &= n_e m_e + n_i m_i \\
\vec{v} &= (n_e m_e \vec{u}_e + n_i m_i \vec{u}_i) / \rho \\
\vec{j} &= -e(n_e \vec{u}_e - Z n_i \vec{u}_i) \\
p &= p_e + p_i
\end{aligned} \tag{12}$$

Where e is the charge of an electron and Z the charge of an ion as a multiple of the electron charge. The first equation is the *total mass density*, the second the *center of mass velocity*, the third the *current density* and the last one describes the *total pressure*.

For a consistent Newtonian theory of MHD, the displacement current $\epsilon_0 \frac{\partial \vec{E}}{\partial t}$ is neglected.

reference to lecture notes arXiv

Finally, the viscosity and heat flow are neglected like in the HD case. Furthermore, for the ideal MHD case the resistivity of the fluid is neglected. The extra equations we need are then:

$$\begin{aligned}\frac{\partial \vec{B}}{\partial t} &= -\nabla \times \vec{E} \\ \nabla \cdot \vec{B} &= 0 \\ \nabla \times \vec{B} &= \mu_0 \vec{j}\end{aligned}$$

We do not need an equation relating the charge distribution to the electric field in the first equation since we assumed the fluid is locally neutral. Furthermore the displacement term in the third equation was neglected.

Adding everything together such as in [REFERENCE TO ONE OF THE COURSES] yields the ideal MHD equations:

reference to
course notes
poedts

$$\begin{aligned}\frac{\partial \rho}{\partial t} + \nabla \cdot (\rho \vec{v}) &= 0 \\ \rho \left(\frac{\partial \vec{v}}{\partial t} + \vec{v} \cdot \nabla \vec{v} \right) + \nabla p - \vec{j} \times \vec{B} &= 0 \\ \frac{\partial p}{\partial t} + \vec{v} \cdot \nabla p + \gamma p \nabla \cdot \vec{v} &= 0 \\ \frac{\partial \vec{B}}{\partial t} - \nabla \times (\vec{v} \times \vec{B}) &= 0\end{aligned}\tag{13}$$

Where

$$\vec{j} = \frac{\nabla \times \vec{B}}{\mu_0}.$$

We need one additional equation which the initial condition has to satisfy:

$$\nabla \cdot \vec{B} = 0$$

which expresses that there are no magnetic monopoles. By acting with $\nabla \cdot$ on the fourth equation in Equation 13 we see that if the initial equation satisfies $\nabla \cdot \vec{B} = 0$, it is automatically satisfied for all later times:

$$\frac{\partial (\nabla \cdot \vec{B})}{\partial t} = 0$$

The equations used by PLUTO in the ideal case have a slightly different form:

reference to
user guide

$$\begin{aligned}\frac{\partial \rho}{\partial t} + \nabla \cdot (\vec{m}) &= 0 \\ \frac{\partial \vec{m}}{\partial t} + \nabla \cdot \left[\vec{m} \vec{v} - \vec{B} \vec{B} + I \left(p + \frac{\vec{B}^2}{2} \right) \right] &= -\rho \nabla \Phi + \rho \vec{g} \\ \frac{\partial \vec{B}}{\partial t} + \nabla \times (c \vec{E}) &= 0 \\ \frac{\partial (E_t + \rho \Phi)}{\partial t} + \nabla \cdot \left[(E_t + p_t + \rho \Phi) \vec{v} - \vec{B} (\vec{v} \cdot \vec{B}) \right] &= \vec{m} \cdot \vec{g}\end{aligned}\tag{14}$$

where, as with the HD equations, $\vec{m} = \rho \vec{v}$ and E_t is again the total energy density, this time with an extra term for the magnetic field:

$$E_t = \rho e + \frac{\rho \vec{v}^2 + \vec{B}^2}{2}$$

$c\vec{E}$ is given by:

$$c\vec{E} = -\vec{v} \times \vec{B}$$

note that the equations do not formally depend on the speed of light, but it is kept in the equations for consistency with the relativistic case.

2.5 Magnetohydrodynamic waves

For our discussion of magnetohydrodynamic waves we rewrite the basic MHD equations into a form which is easier to linearize. We also assume that the plasma is completely homogeneous and in equilibrium. In practice this means that we shall remove the cross products in the original equations as follows

$$\begin{aligned} -\vec{J} \times \vec{B} &= -(\nabla \times \vec{B}) \times \vec{B} = (\nabla \vec{B}) \cdot \vec{B} - \vec{B} \cdot \nabla \vec{B} \\ \nabla \times \vec{E} &= -\nabla \times (\vec{v} \times \vec{B}) = \vec{B} \nabla \cdot \vec{v} + \vec{v} \cdot \nabla \vec{B} - \vec{B} \cdot \nabla \vec{v} \end{aligned} \quad (15)$$

The MHD equations now become

$$\begin{aligned} \frac{\partial \rho}{\partial t} + \nabla \cdot (\rho \vec{v}) &= 0 \\ \rho \frac{\partial \vec{v}}{\partial t} + \rho \vec{v} \cdot \nabla \vec{v} + (\gamma - 1) \nabla(\rho e) + (\nabla \vec{B}) \cdot \vec{B} - \vec{B} \cdot \nabla \vec{B} &= 0 \\ \frac{\partial e}{\partial t} + \vec{v} \cdot \nabla e + (\gamma - 1) e \nabla \cdot \vec{v} &= 0 \\ \frac{\partial \vec{B}}{\partial t} + \vec{v} \cdot \nabla \vec{B} + \vec{B} \nabla \cdot \vec{v} - \vec{B} \cdot \nabla \vec{v} &= 0 \end{aligned} \quad (16)$$

Of course the condition that $\nabla \cdot \vec{B} = 0$ remains. In this form the equations are much easier to linearize:

$$\begin{aligned} \frac{\partial \rho_1}{\partial t} + \nabla \cdot (\rho_0 \vec{v}_1) &= 0 \\ \rho_0 \frac{\partial \vec{v}_1}{\partial t} + (\gamma - 1) \nabla(\rho_1 e_0) + \nabla(\rho_0 e_1) + (\nabla \vec{B}_1) \cdot \vec{B}_0 - \vec{B}_0 \cdot \nabla \vec{B}_1 &= 0 \\ \frac{\partial e_1}{\partial t} + (\gamma - 1) e_0 \nabla \cdot \vec{v}_1 &= 0 \\ \frac{\partial \vec{B}_1}{\partial t} + \vec{B}_0 \nabla \cdot \vec{v}_1 - \vec{B}_0 \cdot \nabla \vec{v}_1 &= 0 \end{aligned} \quad (17)$$

The second one of these equations [Equation 17](#) is the linearized momentum equation. We shall work from this one as it lends itself the most for our discussion of ideal MHD waves. This is because it directly describes flow velocity. Plugging the other three into this equation gives us the essential equation for ideal MHD waves:

$$\frac{\partial^2 \vec{v}_1}{\partial t^2} = \left((\mathbf{b} \nabla)^2 \mathbf{I} + (b^2 + c^2) \nabla \nabla - \mathbf{b} \cdot \nabla (\nabla \mathbf{b} + \mathbf{b} \nabla) \right) \cdot \vec{v}_1 \quad (18)$$

Where

$$c = \sqrt{\frac{\gamma p_0}{\rho_0}} \quad (19)$$

and

$$\vec{b} = \frac{\vec{B}}{\sqrt{\rho_0}} \quad (20)$$

We introduce the constants c and \mathbf{b} as they will be the wave velocities of the solutions of the wave equation Equation 18. The constant c is the acoustic speed known from regular hydrodynamics. The constant \mathbf{b} is known as the *Alfvén* velocity and it is a vector in the same direction as the background magnetic field \mathbf{B}_0 .

Notice that if we set $\mathbf{b} = 0$ Equation 18 becomes

$$\frac{\partial^2 \vec{v}_1}{\partial^2 t} = c^2 \nabla^2 \vec{v}_1$$

which is exactly what we would expect as this is wave equation in the normal hydrodynamic case. This is an important sanity check for our method.

We shall be looking for sinusoidal wave solutions. For now we shall also limit the discussion the waves in the velocity vector field as the waves in the scalar pressure and density fields and the magnetic vector field can easily be expressed in terms of the velocity field using the equations Equation 17. The solutions we look for are of the form

$$\vec{v}_1 = \bar{\mathbf{v}} \exp(i(\omega t - \vec{k} \cdot \vec{x})) .$$

Under the constrain of having to provide sinusoidal wave solutions Equation 18 becomes

$$\left((\omega^2 - (\vec{k} \cdot \mathbf{b})^2) \mathbf{I} - (b^2 + c^2) \vec{k} \vec{k} + \vec{k} \cdot \mathbf{b} (\vec{k} \mathbf{b} + \mathbf{b} \vec{k}) \right) \cdot \bar{\mathbf{v}} = 0 . \quad (21)$$

In order to solve this we need that

$$\det \left((\omega^2 - (\vec{k} \cdot \mathbf{b})^2) \mathbf{I} - (b^2 + c^2) \vec{k} \vec{k} + \vec{k} \cdot \mathbf{b} (\vec{k} \mathbf{b} + \mathbf{b} \vec{k}) \right) = 0 .$$

We shall begin by interpreting this formula in 2D and then see what happens when a third component is added. Without any loss of generality we can assume that $\mathbf{b} = (b, 0)$ and $\vec{k} = (k_x, k_y)$. Broken down into components we then have

$$\begin{pmatrix} -k_x^2 c^2 & -k_y k_x c^2 \\ -k_y k_x c^2 & -k_x^2 (b^2 + c^2) - k_y^2 b^2 \end{pmatrix} \begin{pmatrix} \bar{v}_x \\ \bar{v}_y \end{pmatrix} = -\omega^2 \begin{pmatrix} \bar{v}_x \\ \bar{v}_y \end{pmatrix} \quad (22)$$

Then we see that the determinant of the system is

$$\omega^4 - \omega^2 (k_x^2 b^2 - k_y^2 b^2 - k_y^2 - k_x^2) + b^2 c^2 k_x^2 (1 + k_y^2)$$

of which the roots are $\omega^2 = k^2 \sqrt{b^2 + c^2} (\sqrt{b^2 + c^2} \pm b c k_x)$ where $k^2 = k_x^2 + k_y^2$. These solutions correspond to the so-called fast (+) and slow (-) magnetosonic waves. One can readily see that they are the result of a quite complicated interplay between the hydrodynamic and magnetic sides of the story. To see this better, it helps to lift the problem to 3D.

Take $\vec{b} = (b, 0, 0)$, $\vec{k} = (k_x, k_y, 0)$. There is no loss of generality. Plugging these vectors into [Equation 21](#) we get a slightly different determinant.

$$(\omega^2 - k_x^2 b^2)(\omega^4 - \omega^2(k_x^2 b^2 - k_y^2 b^2 - k_y^2 - k_y^2) + b^2 c^2 k_x^2(1 + k_y^2)) .$$

The roots corresponding to the fast and slow magnetosonic waves are again present (as one would expect). However, there is an extra root $\omega^2 = k_x^2 b^2$. This one is of great interest as it does not contain the same complicated magnetosonic interaction and solely depends on the nature of the magnetic field. The density irregularities only provide the wave's momentum. The restoring force is entirely generated by the tension in the magnetic field.

The wave corresponding to $\omega_A^2 = k_x^2 b^2$ is called the *Alfvén* wave. Notice that its direction corresponds to that of the magnetic field, where $\omega_A = k_x b$ lies in the same direction and $-\omega_A$ in the opposite direction. It should be noted that this solution is non-relativistic. As the magnetic field becomes stronger in comparison to the density the Alfvén wave becomes a regular electromagnetic wave.

Now, the first roots we had - the magnetosonic waves - are combinations of Alfvén waves and ordinary sound waves. There are two types because the Alfvén and sound waves can either be in phase or in antiphase to one another. In the first wave the region of high pressure will correspond to a high magnetic field density, which causes the resulting wave to be driven forward by both ordinary hydrodynamic pressure and the tension of the concentrated magnetic field lines. In the case of the slow wave these same two forces work against each other, slowing the wave.

Magnetohydrodynamic shocks

To derive the Rankine–Hugoniot conditions for MHD shocks, one simply uses [Equation 13](#) as it is already in its Eulerian form and performs the same calculations as for the Rankine–Hugoniot conditions for HD shocks. This yields

$$\begin{aligned} V_S \Delta \rho &= \vec{n} \cdot \Delta(\rho \vec{v}) \\ V_S \Delta(\rho \vec{v}) &= \vec{n} \cdot \Delta(\rho \vec{v} \vec{v} + (p + \frac{B^2}{2}) \mathbf{I} - \vec{B} \vec{B}) \\ V_S \Delta E_t &= \vec{n} \cdot \Delta((\rho \frac{v^2}{2} + \frac{\gamma}{\gamma-1} p + B^2) \vec{v} - \vec{v} \cdot \vec{B} \vec{B}) \\ V_S \Delta \vec{B} &= \vec{n} \cdot \Delta(\vec{v} \vec{B} - \vec{B} \vec{v}) \end{aligned} \tag{23}$$

2.6 Units

The PLUTO code works, in general, with dimensionless code-units. This is done by defining a unit density ρ_0 , unit velocity v_0 and unit length L_0 . From these, unit time can be defined as $t_0 = L_0/v_0$. Inspired by [Equation 19](#) and [Equation 20](#) we define $p_0 = \rho_0 v_0^2$ and $B_0 = v_0 \sqrt{4\pi\rho_0}$. Next, we use the substitutions $v_0 \vec{v}_u = \vec{v}$, $\rho_0 \rho_u = \rho$, $L_0 \vec{x}_u = \vec{x}$, $t_0 t_u = t$, $p_0 p_u = p$ and $B_0 \vec{b}_u = \vec{B}$ in [Equation 13](#). Here the subscript u denotes that these numbers or vectors have no units, the units are contained in the factors with subscript 0.

$$\begin{aligned}
& \frac{\rho_0}{t_0} \frac{\partial \rho_u}{\partial t_u} + \frac{\rho_0 v_0}{L_0} \nabla \cdot (\rho_u \vec{v}_u) = 0 \\
& \frac{\rho_0 v_0^2}{L_0} \rho_u \left(\frac{\partial \vec{v}_u}{\partial t_u} + \vec{v}_u \cdot \nabla_u \vec{v}_u \right) + \frac{\rho_0 v_0^2}{L_0} \nabla_u p_u - \frac{\rho_0 v_0^2}{L_0} \frac{\nabla_u \times \vec{B}_u}{\mu_0} \times \vec{B}_u = 0 \\
& \frac{p_0 v_0}{L_0} \frac{\partial p_u}{\partial t_u} + \frac{p_0 v_0}{L_0} \vec{v}_u \cdot \nabla_u p_u + \frac{p_0 v_0}{L_0} \gamma p_u \nabla_u \cdot \vec{v}_u = 0 \\
& \frac{B_0 v_0}{L_0} \frac{\partial \vec{B}_u}{\partial t_u} - \frac{B_0 v_0}{L_0} \nabla_u \times (\vec{v}_u \times \vec{B}_u) = 0
\end{aligned} \tag{24}$$

We see that all the units drop out of the equations and we are left with a set of dimensionless equations. This highlights an important fact for ideal MHD: the equations are scale-invariant. For the behaviour of waves the absolute scales are not important, but only the relative magnitude of the characteristic scales for a wave. When we have a wave with wavelength λ_1 and frequency f_1 , it will show the same behaviour as a wave with wavelength λ_2 and frequency f_1/λ_1 in the same medium (that is, same Alfvén speed).

Because the ideal MHD equations are in fact dimensionless (without sources), we can carry out the simulations in dimensionless units and later scale our results to match conditions as found in e.g. the solar corona, under the condition that the relative magnitudes of ρ_0 , v_0 and L_0 are correct.

3 Shock waves

As a testcase to learn how to use the PLUTO software we simulated hydrodynamic and magnetohydrodynamic blastwaves in a 2D domain. The initial condition for the simulations is a circle with radius 0.3 (in code units) with higher pressure. The pressure outside the circle is 1, in code units. For the pressure inside the circle two scenarios were simulated. One with a large pressure difference, where the pressure inside the circle is 5. In the other scenario a lower pressure difference was used: the pressure inside the circle was 1.5. The reason for using different pressure differences is to see the non-linear effects in the shock-wave with high pressure difference.

3.1 Hydrodynamic blastwave

In [Figure 1](#) the pressure profile of both scenarios is plotted for the initial condition and two frames right after the start of the simulation. In [Figure 2](#) the profile is plotted for later times.

Figure 1: Pressure profile for a blastwave in an ideal fluid at different times. The top row start with the larger pressure difference of 5/1, the bottom row is the blastwave with smaller pressure difference of 1.5/1.

Figure 4: the speed of the wave as a function of time, along the x -axis. The dots represent the speed calculated from the simulation data by deriving the function $x(t)$ that represents the position of the wave front. The lines represent the theoretical shock speed in a Riemann-problem with as high pressure the highest pressure in the domain, and low pressure 1.

Figure 2: Pressure profile for a blastwave in an ideal fluid at larger timescales. Initial conditions for each row are the same as in [Figure 1](#).

test

Figure 3: The wave speed as a function of the angle between the x -axis and the line connecting a point on the wave-front with the center of the domain. The wavespeed is calculated from the simulation data.
